

## Childhood Cancer Survivor Study Concept Proposal

### I. Title:

Physical activity as a predictor of neurocognitive outcomes in adult survivors of childhood cancers.

**Working Groups:** Psychology (Primary), Cancer Control (Secondary), Chronic Disease (Secondary)

Proposed investigators will be:

### II. Background and Rationale:

Cancer occurs in 17 out of every 100,000 individuals in the United States under the age of 20 [1]. With advances in the treatment of pediatric cancers, survival rates have improved to approximately 80%, leading to a growing population of adult survivors of childhood cancer [1]. Notably, the majority of these cases require invasive treatments such as chemotherapy or irradiation, which put survivors at risk for late effects, such as second cancers, endocrinopathies, and cognitive deficits [2].

Cognitive dysfunction affects one third or more of childhood cancer survivors, and may continue to progress for years after the termination of treatment [3-7]. Although the severity of impairment has been strongly associated with exposure to specific chemotherapy agents and cranial irradiation, evidence also exists for direct effects of both CNS and non-CNS cancers on cognitive function in adults [8-12]. Moreover, cognitive difficulties may be exacerbated by comorbid chronic health conditions [13-14]. Dysfunction in childhood cancer survivors has been characterized by a decline in full scale intelligence quotient (FSIQ), and/or impairment in core functional domains, such as attention, working memory, executive function, processing speed, or visuomotor integration [15-19]. Survivors have reported neurocognitive problems in day-to-day living, and have demonstrated greater challenges in academic, vocational, social, and psychological aspects of their lives [20-23].

Survivors of childhood cancer have reported lower engagement in physical activity than healthy controls, as well as greater declines in activity over time [24]. These lower rates of activity have been associated with the receipt of a cancer diagnosis, reduced psychosocial well-being, greater somatic symptoms, and

an elevated risk for secondary chronic health conditions and mortality [25-28]. Notably, engagement in physical activity has been associated with hippocampal neurogenesis in rodents, as well as with neuroimaging indices of brain health and better cognitive function in a variety of healthy and clinical populations [29], suggesting that this is an important variable to consider in studying the cognitive sequelae of childhood cancer. These relationships may be mediated by changes to adiposity, with negative relationships observed between Body Mass Index (BMI) and cognitive performance in healthy children, adolescents and adults [30]. Meta-analyses have noted significant relationships between physical activity and measures of attention, memory, motor control, spatial cognition, and processing speed, with particularly strong associations observed for executive functions [29, 31]. Although the largest effect sizes have been observed for aerobic exercise [31-32], efficacy has been demonstrated for a range of interventions, leaving it unclear as to what intensity and quantity of physical activity is optimal for the prevention and/or treatment of cognitive deficits.

In the adult cancer literature, higher levels of physical activity have been associated with better neuropsychological outcomes in both cross-sectional and intervention studies [33]. Survivors of childhood cancer reporting higher levels of leisure-time physical activity have also endorsed more positive ratings of cognitive function, social function, and overall health-related quality of life [34]. Moreover, increased hippocampal volume and white matter fractional anisotropy, as well as improved reaction time have been observed in children treated with radiation for brain tumors following a 12-week aerobic exercise intervention [35]. However, no large-scale study has examined whether physical activity predicts late cognitive effects in childhood cancer survivors more broadly. In the current study, we aim to examine associations between physical activity and neurocognitive outcomes in a cohort of North American childhood cancer survivors who have taken part in the Childhood Cancer Survivor Study (CCSS), and to explore BMI and secondary chronic health conditions as factors influencing this relationship.

### **III. Objective/Specific aims/Research Hypotheses:**

Aim 1. To examine associations between persistent physical activity (i.e. meeting CDC guidelines) and neurocognitive outcomes on the CCSS-NCQ at follow-up in survivors and siblings, after controlling for relevant covariates.

Hypothesis. Those who have consistently met CDC guidelines from baseline to follow-up will show fewer symptoms on the NCQ or lower rates of impairment than those who have been inconsistent, or have consistently not met guidelines. This relationship is anticipated to occur in both survivors and their siblings; however, we anticipate a stronger relationship in survivors.

Although the literature provides a rationale for those engaging in higher levels of activity to demonstrate fewer symptoms across each of the NCQ domains (Emotional Regulation, Memory, Organization, and Task Efficiency), the Memory domain (which captures both working memory and long-term memory) and Organization domain are hypothesized to be most strongly associated with one's engagement in physical activity.

Aim 2. To explore associations between the intensity of physical activity, the quantity of physical activity (minutes per week) and neurocognitive outcomes on the CCSS-NCQ in survivors and siblings, after controlling for relevant covariates.

Hypothesis. Those engaging in more intense and more frequent activity will demonstrate fewer symptoms on the NCQ scores or lower rates of impairment. This relationship is anticipated to occur in both survivors and their siblings; however, we anticipate a stronger relationship in

survivors. Similar to Aim 2, out of the neurocognitive domains measured, we anticipate that Memory will be most strongly associated with physical activity intensity and frequency.

Aim 3. To evaluate BMI as a mediator of the relation between persistence of physical activity and neurocognitive outcome on the CCSS-NCQ.

Hypothesis. BMI will partially mediate this relationship; however, physical activity is anticipated to predict NCQ symptomatology over and above BMI. A negative relationship is anticipated to occur between PA and BMI, as well as in the direct relationship between PA and NCQ symptomatology. The relationship between BMI and NCQ symptom reporting is anticipated to be positive.

Aim 4. To evaluate physical activity as a mediator of the association between chronic health conditions (e.g. cardiovascular, respiratory) and neurocognitive outcome on the CCSS-NCQ.

Hypothesis. Physical activity will account for a modest proportion of the relationship between chronic health conditions and symptoms on the NCQ. The presence of a chronic health condition is anticipated to be associated with lower PA, which in turn, is anticipated to have a negative association with NCQ symptomatology. Moreover, having a chronic health condition is expected to be positively associated with NCQ symptomatology.

Aim 5. To examine associations between patterns of PA and change in NCQ symptoms over time, using latent cluster analyses.

Hypothesis. We anticipate that survivors will cluster in the following pattern:

- Consistently high PA and healthy BMI
- Consistently high PA and high BMI
- Variable PA over time and healthy BMI
- Variable PA over time and high BMI
- Consistently low PA and high BMI
- Consistently low PA and healthy BMI

Moreover, we expect that clusters engaging in greater and more consistent PA, with healthy BMI scores, will be more likely to demonstrate stability or improvement in NCQ symptoms over time.

#### **IV. Analysis Framework:**

##### **Population**

We propose to conduct our analysis on the original and expanded CCSS survivor cohorts. We propose to also include siblings as a comparison group for the CCSS-NCQ.

##### **Subject population**

Survivors and siblings from the original and expanded cohorts who completed physical activity information at baseline and follow-up (FU), as well as the CCSS-NCQ at FU. To allow for greater consistency in the timespan between baseline and FU measurements between the original and expanded cohorts, FU will be defined as FU2 for the original cohort and as FU5 for the expanded cohort.

## Measures

### Independent variables:

- Physical activity
  - Meeting CDC guidelines
    - Meeting CDC guidelines = >75 mins of vigorous; >150 mins moderate per week
    - Group participants based on persistence of PA from baseline to FU.
    - Consistently active (yes/yes); Inconsistently active (yes/no; no/yes); Consistently inactive (no/no)
    - For baseline – can only get a rough estimate of #minutes/per week engaged in vigorous exercise
      - **< 18 yrs Baseline: Original cohort N.5; Expanded cohort O1**
        - “On how many of the past 7 days did your child exercise or do sports for at least 20 minutes that made him/her sweat or breathe hard”
      - **> 18 yrs Baseline: Original cohort N.9; Expanded cohort O15**
        - “How many days (/7) did you exercise or do sports for at least 20 minutes that made you sweat or breathe hard”
      - If 4 or more days – yes, meeting guidelines
    - FU – Given # minutes of vigorous and moderate activity per week
      - Classify as meeting CDC guidelines if >75 vigorous, or >150 moderate per week (**FU2 D.2-7; FU5 N.16-21**)
        - If <75 vigorous and <150 moderate – count vigorous minutes toward moderate total
  - Intensity of physical activity = (#days per week vigorous \* 9) + (#days per week moderate \* 5)
    - **FU2 D.3, D.6; FU5 N.17, N.20**
  - Quantity = (#days per week \* minutes per day vigorous) + (# days per week \* minutes per day moderate)
    - **FU2 D.2-D.7; FU5 N.16-N.21**
- BMI = (weight in pounds / (height in inches \* height in inches)) \* 703
  - **FU2 7,8; FU5 A.1-2**
- Chronic condition (yes/no) at any time point
  - Yes = existing grade 3-4 “relevant” conditions

| Relevant               | “Not relevant”                   |
|------------------------|----------------------------------|
| Cardiovascular         | Neurologic – Memory problems     |
| Respiratory            | (redundant)                      |
| Musculoskeletal        | GI, Renal (not listed elsewhere) |
| Neurological           | Speech                           |
| Hematologic            | Hearing                          |
| Infectious/Immunologic |                                  |
| Diabetes               |                                  |
| Renal – dialysis       |                                  |
| Endocrine              |                                  |
| Hepatitis              |                                  |
| Vision                 |                                  |
| Secondary malignancy   |                                  |

Dependent variable:

- CCSS-NCQ
  - Raw scores
    - Composite, task efficiency, emotion regulation, organization, memory)
    - **FU2 J.1-25; FU5 Q.1-33**
  - Impairment (yes/no)
    - Impaired = symptom level reported in  $\leq 10\%$  of the sibling normative sample Composite, task efficiency, emotion regulation, organization, memory
  - Change
    - $(x_2 - x_1) > SE \text{ of } (x_2 - x_1) \text{ for sibling sample}$ 
      - If YES (with increased symptoms) = cognitive decline
      - If YES (with decreased symptoms) or if NO = no decline
    - Composite, task efficiency, emotion regulation, organization, memory

Covariates:

- Health behaviours
  - Tobacco use – **FU2 L.2; FU5 N.9**
    - Do you smoke cigarettes now (yes/no)
- Demographics
  - Age – **FU Date – Baseline A.1 (DOB)**
  - Education – **FU2 Question 1; FU5 A.4**
    - What is the highest grade or level of schooling you have completed (ordinal scale)
  - Race – **Original cohort Baseline A.4; Expanded cohort Baseline A.5**
  - Sex – **Baseline A.2**
- Clinical variables
  - Age at diagnosis
  - Time since diagnosis
  - Diagnosis
  - Treatment
    - CNS radiation dose
    - Mediastinal radiation dose
    - Chemotherapy dose (antimetabolites, anthracyclines, alkylating agents, corticosteroids)
    - Bone marrow transplant
  - Psychiatric symptomatology – BSI composite (**FU2 G.1-18; FU5 L.1-18**)

## Analyses

- Descriptive statistics and comparison of demographics across childhood cancer survivors and siblings. T-test or chi-square, as appropriate.
- Covariance matrix – Covariates vs. PA and NCQ
  - Include relevant covariates ( $p < 0.05$ ) in subsequent analyses
- **Aim 1** (Tables 2-5)
  - Multivariable regression
    - Predictors: PA (persistence; baseline  $\rightarrow$  FU), Group (survivors vs. siblings)
    - Interaction (PA & Group)
    - Outcome: NCQ-raw and NCQ-impairment at FU (composite, task efficiency, emotion regulation, organization, memory)
    - Covariates: age at NCQ (and others identified in covariance matrix)
  - This analysis will be run separately for CNS tumor and non-CNS tumor survivors because of possible collinearity between PA and NCQ in the CNS group.

- **Aim 2** (Tables 5-9)
  - Multivariable regression
    - Predictors: PA (quantity at FU), Group (survivors vs. siblings)
    - Interaction (PA & Group)
    - Outcome: NCQ-raw and NCQ-impairment at FU (composite, task efficiency, emotion regulation, organization, memory)
    - Covariates: age at NCQ (and others identified in covariance matrix)
  - Multivariable regression
    - Predictors: PA (intensity at FU), Group (survivors vs. siblings)
    - Interaction (PA & Group)
    - Outcome: NCQ-raw and NCQ-impairment at FU (composite, task efficiency, emotion regulation, organization, memory)
    - Covariates: age at NCQ (and others identified in covariance matrix)
- **Aim 3** (Table 10)
  - Mediation analysis
    - Predictor: PA (as defined in Aim 1),
    - Mediator: BMI at FU
    - Outcomes: NCQ-raw at FU (composite, task efficiency, emotion regulation, organization, memory)
    - Covariates: age at NCQ (and others identified in covariance matrix)
- **Aim 4** (Table 11)
  - Mediation analysis
    - Predictor: Presence of chronic condition [yes/no]
    - Mediator: PA (as defined in Aim 1)
    - Outcome: NCQ-raw at FU (composite, task efficiency, emotion regulation, organization, memory)
    - Covariates: age at NCQ (and others identified in covariance matrix)
- **Aim 5\***original cohort, survivors only (Table 12-14)
  - Latent profile analysis in a random sample of half the original cohort. The remainder of the cohort will be used as a validation sample. We will subsequently explore demographic, disease, and treatment predictors of cluster membership, as well as how effectively cluster membership predicts meaningful change on the NCQ.
    - Variables: PA intensity (baseline, FU2, FU5), BMI (FU5)
    - Run validation analysis with remaining 50% of sample
  - Multinomial regression analysis
    - Predictors
      - Demographic: sex, age at FU5, educational attainment
      - Disease: diagnosis, age at diagnosis
      - Treatment: chemotherapy exposure ([yes/no], antimetabolites, anthracyclines, alkylating agents, corticosteroids), radiation (cranial [yes/no], non-cranial [yes/no]), cranial radiation dose
      - Presence of chronic health condition [yes/no]
      - Clinically significant psychiatric symptomatology [yes/no]
    - Outcome: cluster membership
  - Regression
    - Predictor: cluster membership
    - Outcome: change in NCQ [decline/no decline]

Table 1. Characteristics of participants who completed the NCQ at follow-up in the original and expanded cohorts, (i.e. study sample) and survivors excluded from analyses due to missing NCQ and/or PA data.

| Characteristics                            | Survivors |   | Survivors excluded |   | p | Siblings |   | p |
|--|-----------|---|--------------------|---|---|----------|---|---|
|  | N         | % | N                  | % |   | N        | % |   |
| Sex  |           |   |                    |   |   |          |   |   |
| Male                                       |           |   |                    |   |   |          |   |   |
| Female                                     |           |   |                    |   |   |          |   |   |
| Race                                       |           |   |                    |   |   |          |   |   |
| White                                      |           |   |                    |   |   |          |   |   |
| Black                                      |           |   |                    |   |   |          |   |   |
| Other                                      |           |   |                    |   |   |          |   |   |
| Ethnicity                                  |           |   |                    |   |   |          |   |   |
| Hispanic                                   |           |   |                    |   |   |          |   |   |
| Non-Hispanic                               |           |   |                    |   |   |          |   |   |
| Age at baseline                            |           |   |                    |   |   |          |   |   |
| 18-29 yrs                                  |           |   |                    |   |   |          |   |   |
| 30-39 yrs                                  |           |   |                    |   |   |          |   |   |
| 40-54 yrs                                  |           |   |                    |   |   |          |   |   |
| Education                                  |           |   |                    |   |   |          |   |   |
| < 12 yrs                                   |           |   |                    |   |   |          |   |   |
| High school graduate                       |           |   |                    |   |   |          |   |   |
| Some college                               |           |   |                    |   |   |          |   |   |
| College graduate                           |           |   |                    |   |   |          |   |   |
| Household income                           |           |   |                    |   |   |          |   |   |
